WORKING PAPERS

Power Move: Solar Adoption Among Firms
Job Market Paper

Fossil fuel consumption for electricity and heat generation remains a major contributor to global emissions, yet firm adoption of renewable energy has been slower than necessary to achieve climate goals. This paper investigates what drives firm-level adoption of distributed solar generation by leveraging unique microdata on solar panel installations across firms. To identify the causal effects of economic incentives on adoption decisions, I exploit variation generated by an energy price subsidy that differentially affected firms' cost-benefit calculations for solar investment. I find evidence of a positive substitution effect: firms are more likely to adopt solar generation when grid energy prices are higher, consistent with firms seeking to reduce their exposure to energy costs. To quantify the relative importance of different price and cost channels, I estimate a discrete-continuous choice model that jointly captures both the adoption decision and the capacity choice. The results reveal that while energy price subsidies did account for a significant increase in solar adoption, firms appear to be more responsive to high upfront investment costs than to ongoing energy prices. I find that solar panel price subsidies would be more effective at expanding adoption among firms, with important implications for the design of climate policies aimed at accelerating the transition to renewable energy.

Oligopsony Power in Labor Markets: Evidence from a Payroll Tax Reform

Understanding non-competitive behavior in labor markets has become crucial to gain insight into labor market dynamics, and estimating labor supply wage elasticities can help determine the existence of oligopsony power. By building on Manning (2003), I use matched employer-employee data, and take advantage of sector-specific shocks to payroll taxes, to estimate labor supply wage elasticities for the Brazilian labor market. I estimate separation and recruitment elasticities using an IV approach that allows for the identification of exogenous variation in wages through the reform on payroll taxes implemented in Brazil, which represents shocks to labor demand. While standard OLS estimates are low (and unrealistic) as in the recent literature, estimates using the IV approach are much more reasonable. The results indicate that there exists considerable labor market power by firms in Brazil, with a market-level elasticity of 1.4 and a firm-level elasticity of 4.4. Finally, I evaluate whether oligopsony power is different between skill levels, as well as between more or less urbanized and informal municipalities. I find that firms exert higher markdowns for low-skill workers, and that higher labor market power is correlated with lower urbanization and higher informality.
